

CPSC 340: Machine Learning and Data Mining

Sparse Matrix Factorization
Bonus Slides

“Synthesis” View vs. “Analysis” View

- We said that PCA finds hyper-plane minimizing distance to data x_i .
 - This is the “synthesis” view of PCA (connects to k-means and least squares).

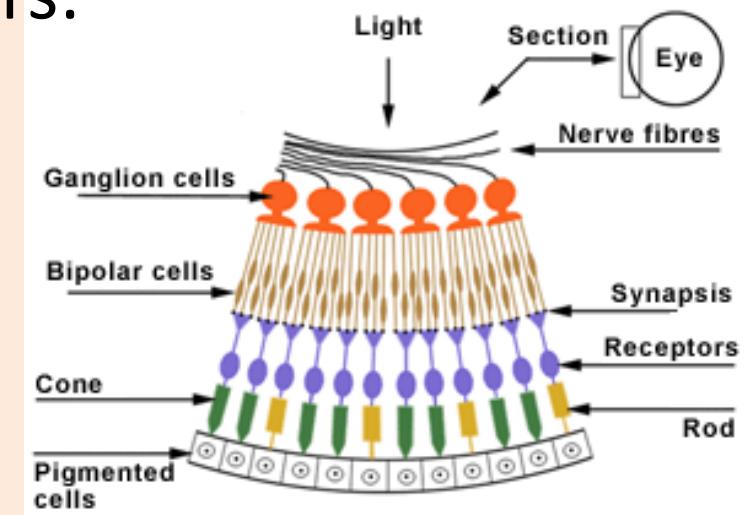

- “Analysis” view when we have orthogonality constraints:
 - PCA finds hyper-plane maximizing variance in z_i space.
 - You pick W to “explain as much variance in the data” as possible.

Colour Opponency in the Human Eye

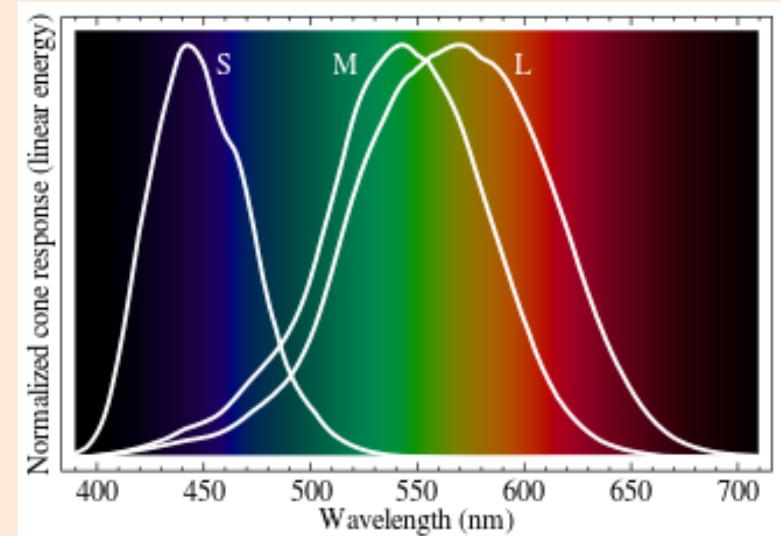

- Classic model of the eye is with 4 photoreceptors:

- Rods (more sensitive to brightness).
- L-Cones (most sensitive to red).
- M-Cones (most sensitive to green).
- S-Cones (most sensitive to blue).

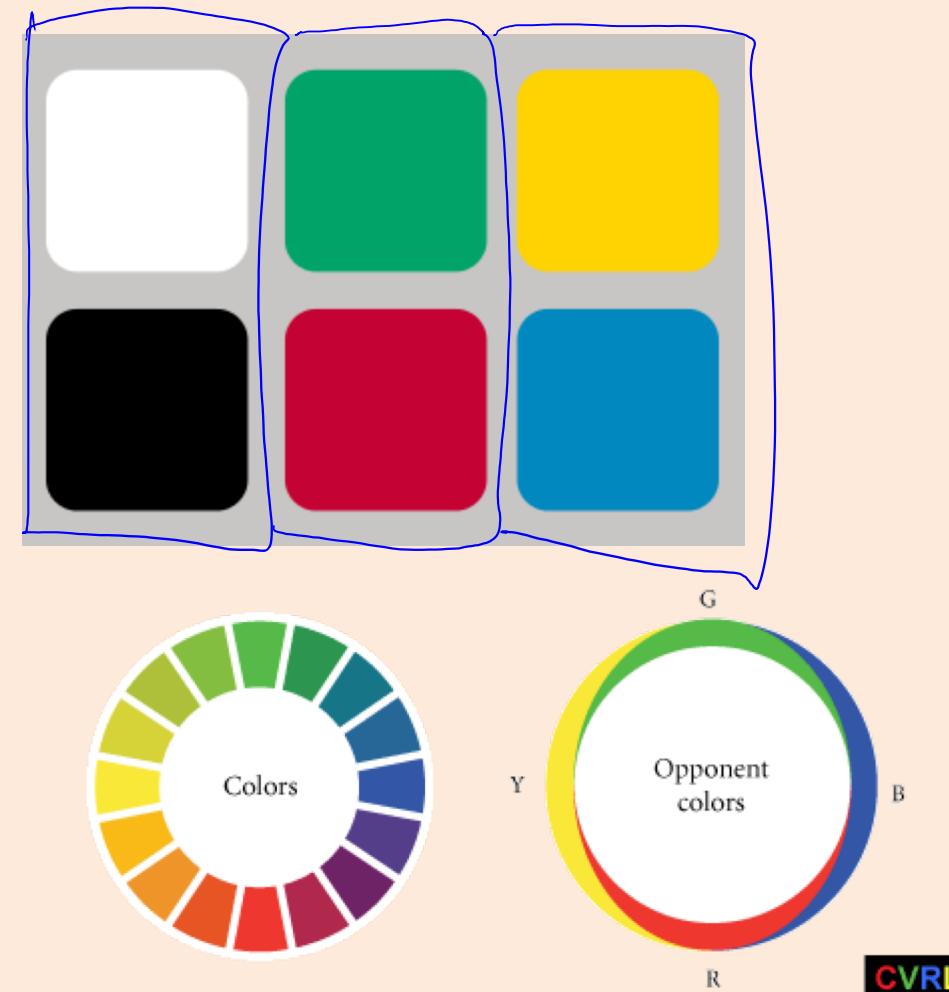

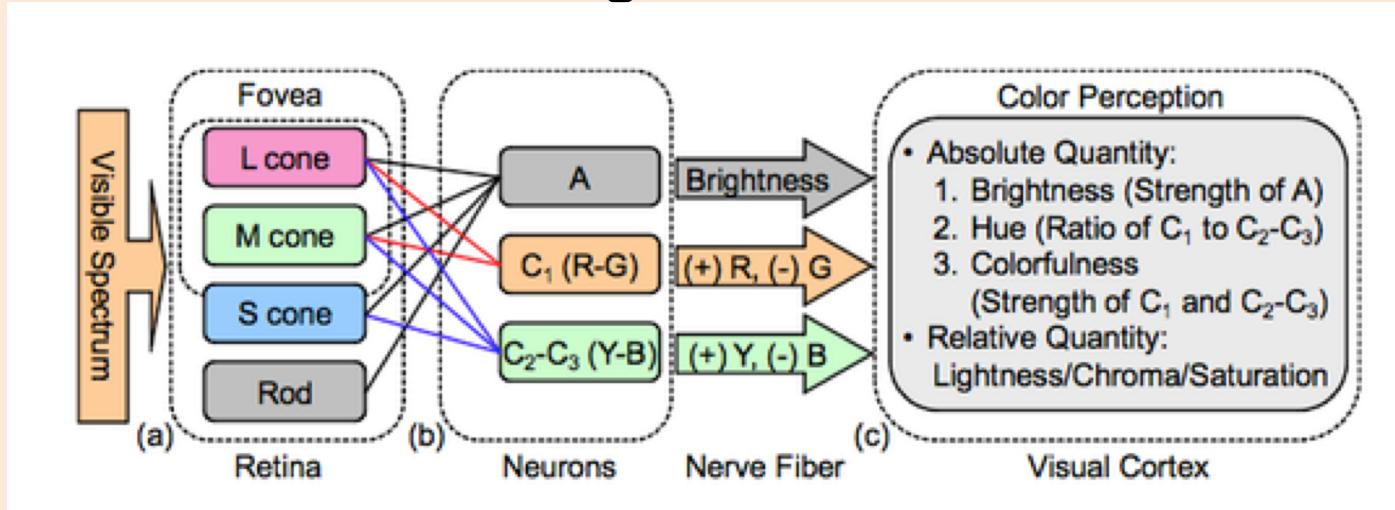

- Two problems with this system:

- Not orthogonal.
 - High correlation in particular between red/green.
- We have 4 receptors for 3 colours.

Colour Opponency in the Human Eye

- Bipolar and ganglion cells seem to code using “opponent colors”:
 - 3-variable orthogonal basis:

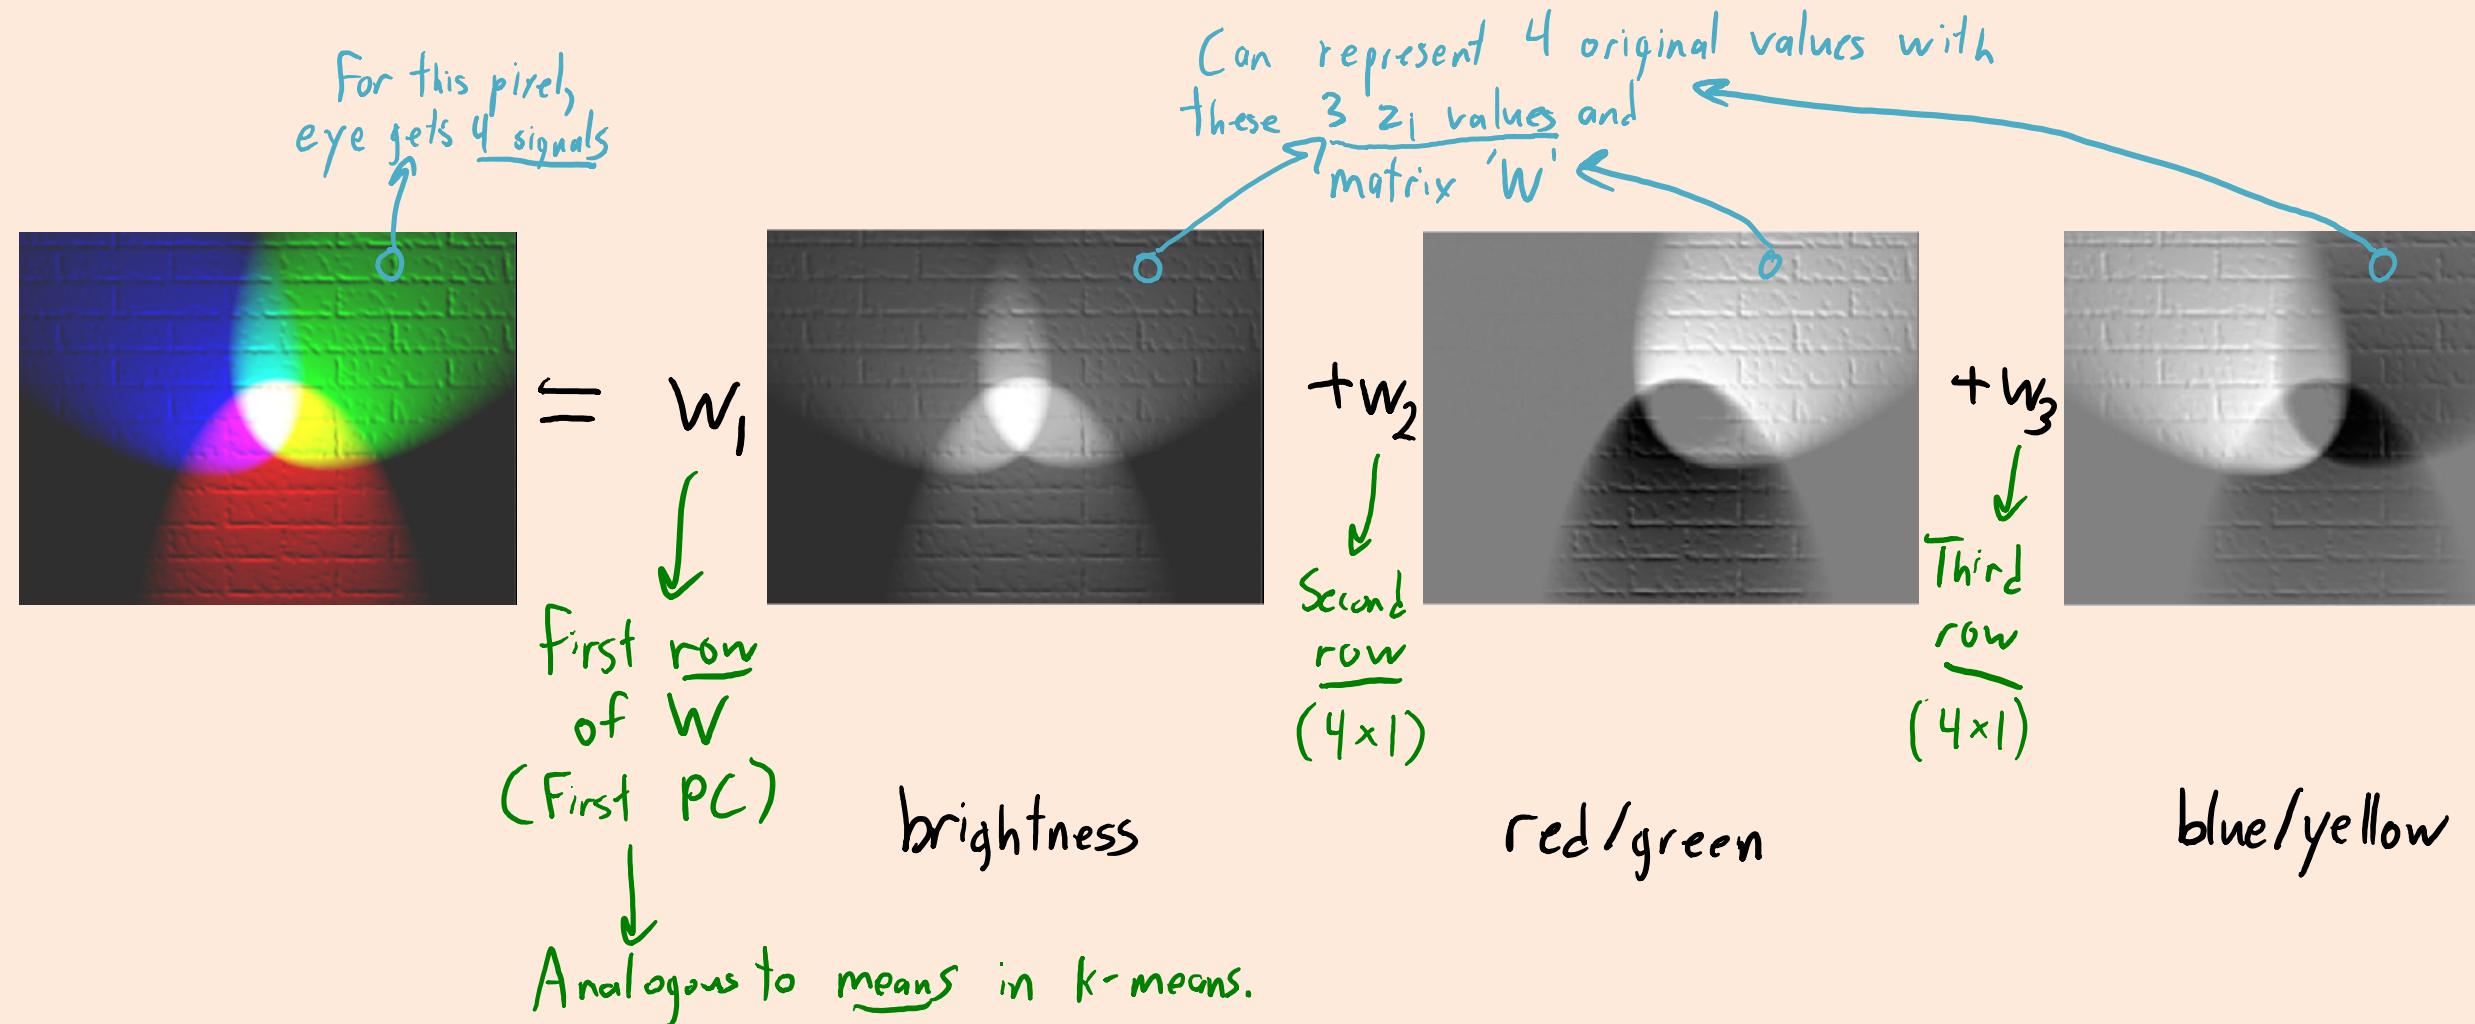

- This is similar to PCA ($d = 4$, $k = 3$).

Colour Opponency Representation

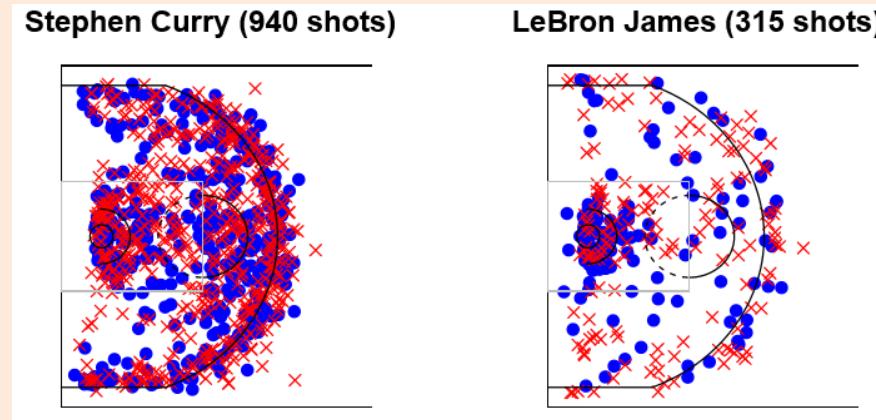

Representing Faces

- Why sparse coding?
 - “Parts” are intuitive, and brains seem to use sparse representation.
 - Energy efficiency if using sparse code.
 - Increase number of concepts you can memorize?
 - Some evidence in fruit fly olfactory system.

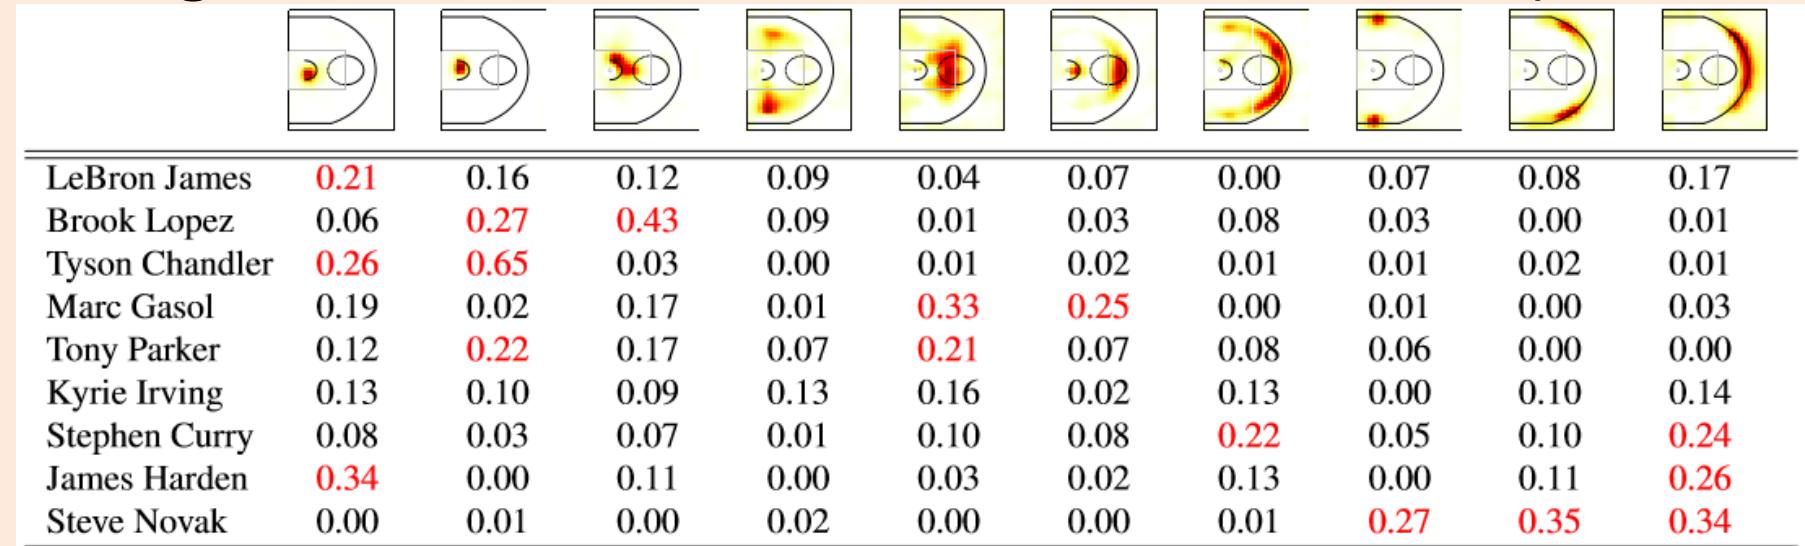

Application: Sports Analytics

- NBA shot charts:

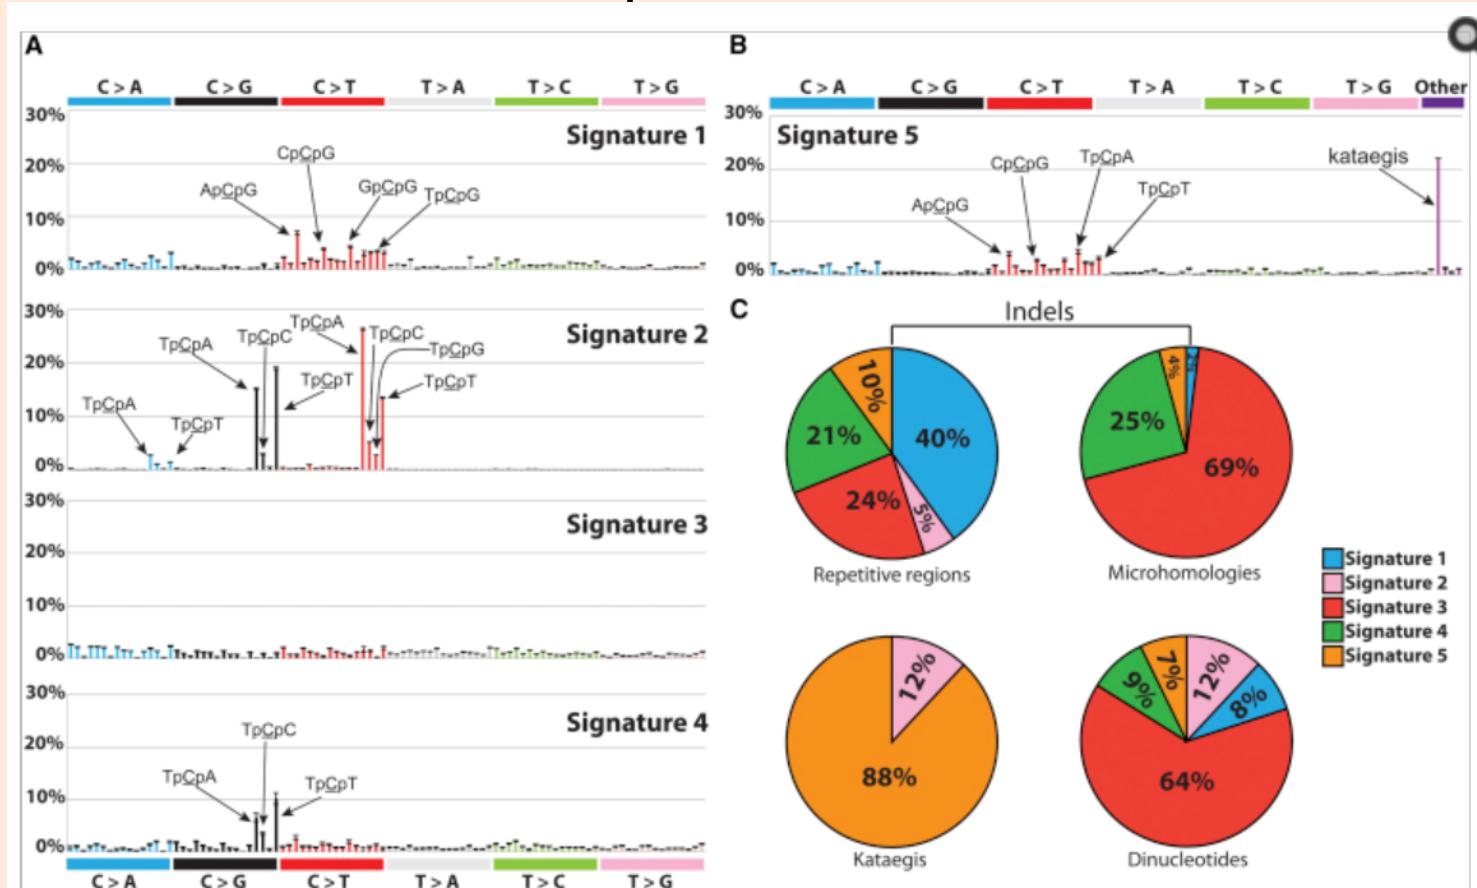

- NMF (using “KL divergence” loss with k=10 and smoothed data).
 - Negative values would not make sense here.

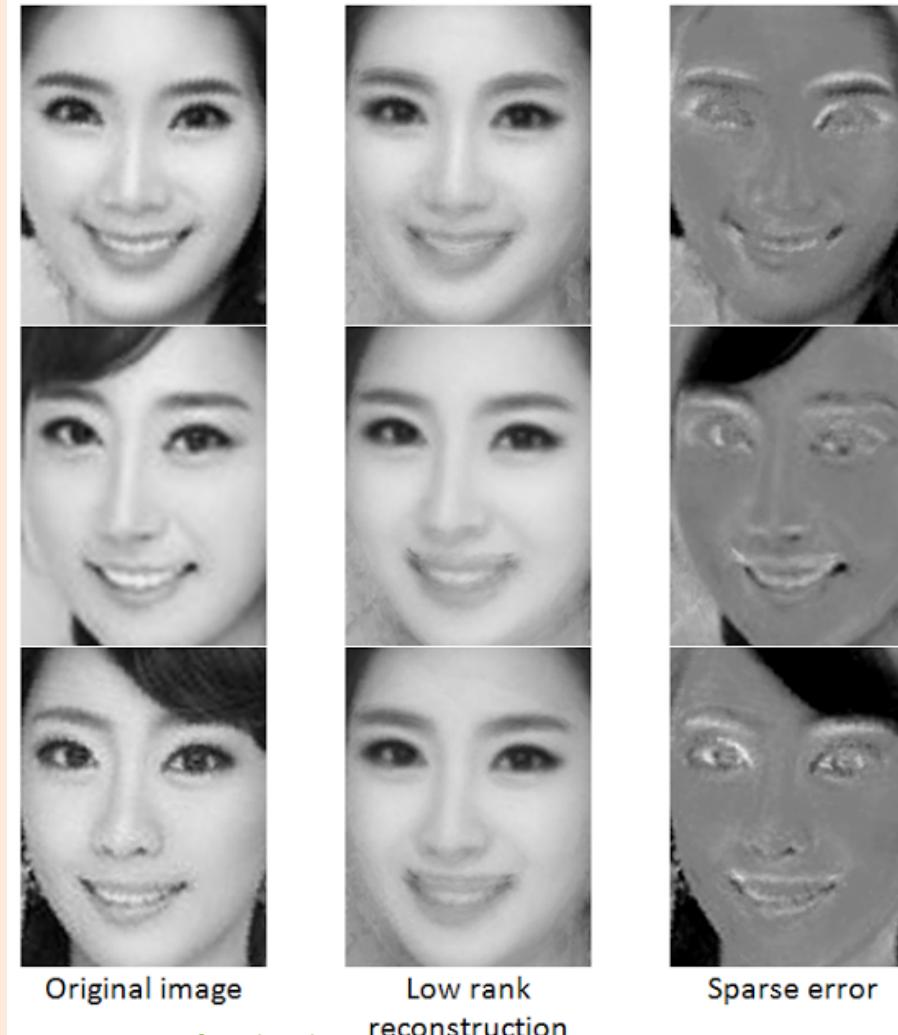

Application: Cancer “Signatures”

- What are common sets of mutations in different cancers?
 - May lead to new treatment options.

Robust PCA

- Miss Korea contestants and robust PCA:

Sparse Matrix Factorization

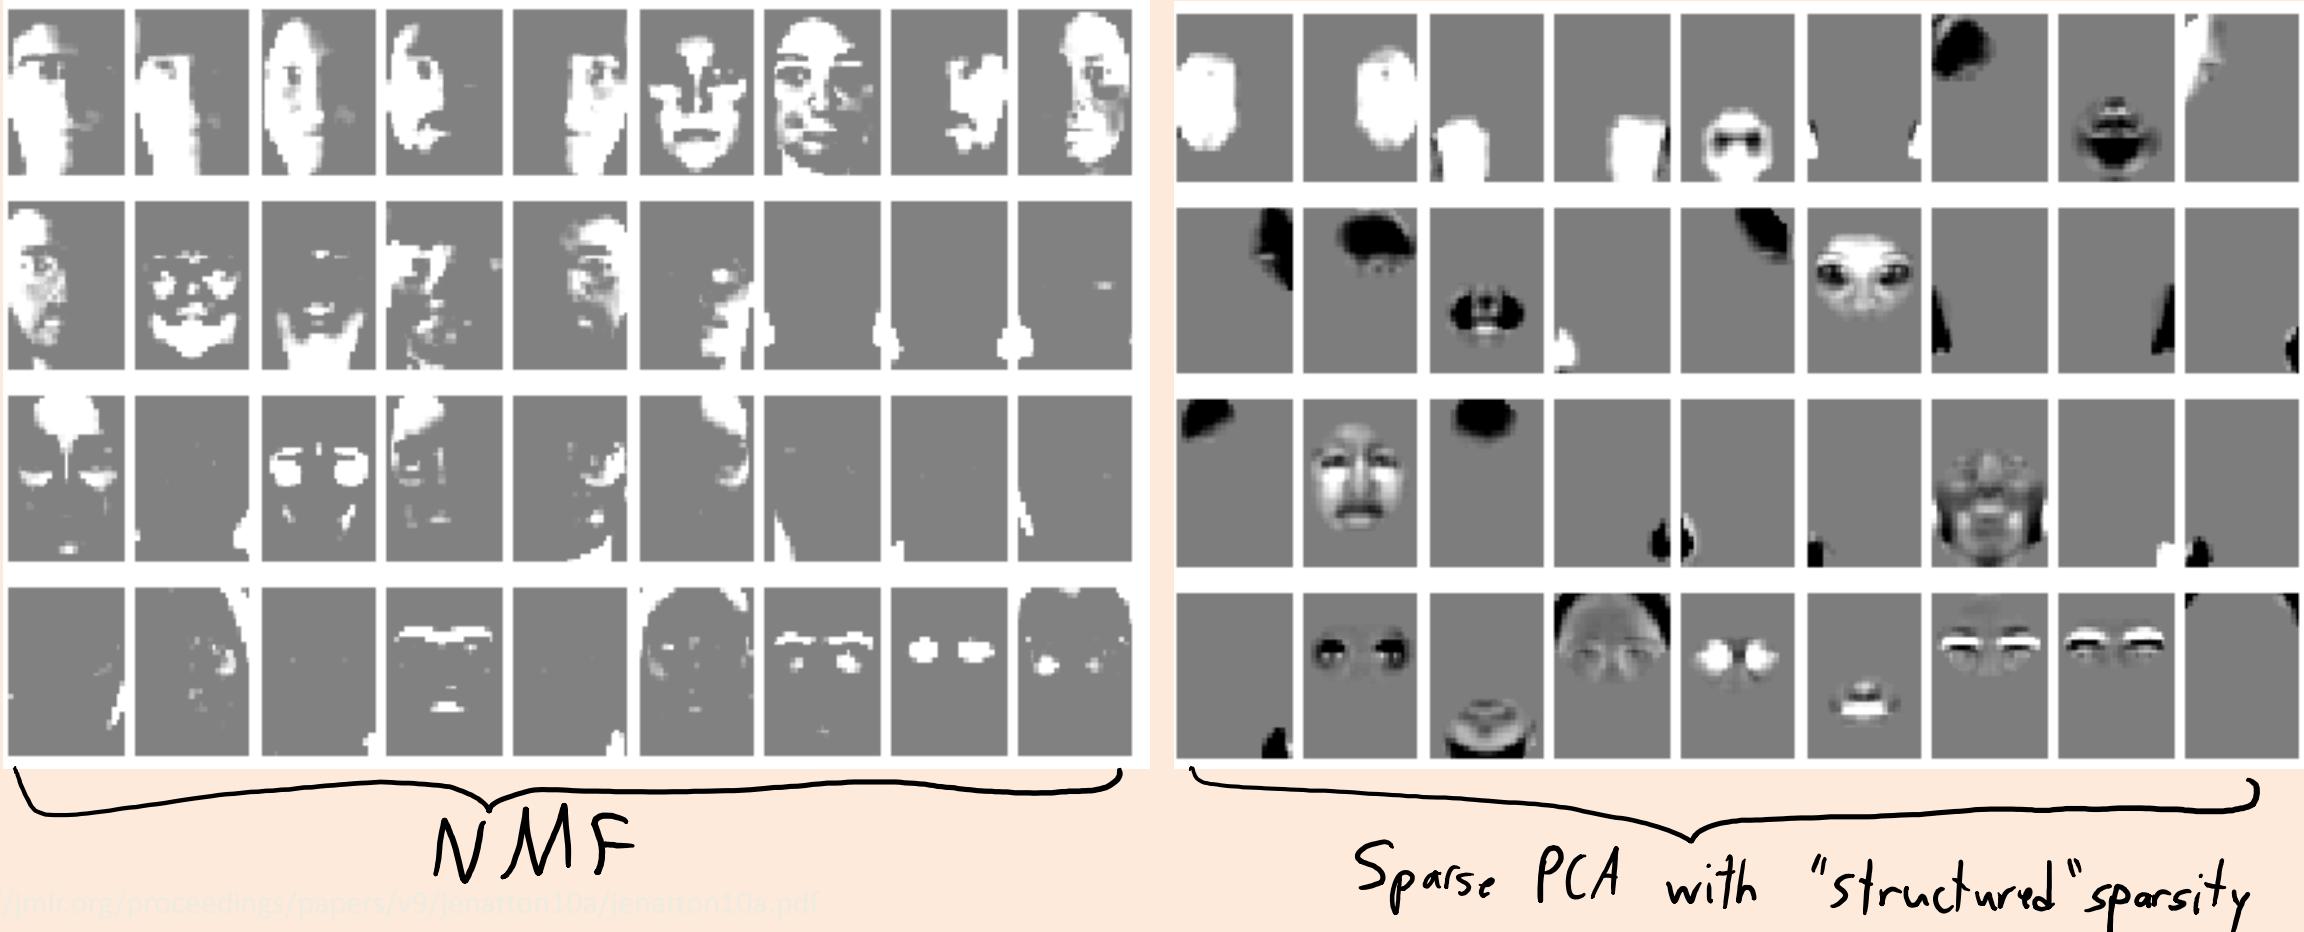

- Instead of non-negativity, we could use L1-regularization:

$$f(W, Z) = \frac{1}{2} \|ZW - X\|_F^2 + \frac{\lambda_1}{2} \sum_{i=1}^n \|z_i\|_1 + \frac{\lambda_2}{2} \sum_{j=1}^d \|w_j\|_1$$

- Called **sparse coding** (L1 on ‘Z’) or **sparse dictionary learning** (L1 on ‘W’).
- Many variations exist:
 - Mixing L2-regularization and L1-regularization.
 - Or normalizing ‘W’ (in L2-norm or L1-norm) and regularizing ‘Z’.
 - **K-SVD** constrains each z_i to have at most ‘k’ non-zeroes:
 - K-means is special case where $k = 1$.
 - PCA is special case where $k = d$.

Recent Work: Structured Sparsity

- “Structured sparsity” considers dependencies in sparsity patterns.
 - Can enforce that “parts” are convex regions.

Proof: “Synthesis” View = “Analysis” View ($WW^T = I$)

- The variance of the z_{ij} (maximized in “analysis” view):

$$\begin{aligned}
 \frac{1}{n^k} \sum_{i=1}^n \|z_i - \mu_z\|^2 &= \frac{1}{n^k} \sum_{i=1}^n \|Wx_i\|^2 \quad (\mu_z = 0 \text{ and } z_i = Wx_i \text{ if } \|W_i\| = 1 \text{ and } W_i^T W_i = 0) \\
 &= \frac{1}{n^k} \sum_{i=1}^n x_i^T W^T W x_i = \frac{1}{n^k} \sum_{i=1}^n \text{Tr}(x_i^T W^T W x_i) = \frac{1}{n^k} \sum_{i=1}^n \text{Tr}(W^T W x_i x_i^T) \\
 &= \frac{1}{n^k} \text{Tr}(W^T W \sum_{i=1}^n x_i x_i^T) = \frac{1}{n^k} \text{Tr}(W^T W X^T X)
 \end{aligned}$$

linearity of trace “cyclic” property of trace

- The distance to the hyper-plane (minimized in “synthesis” view):

$$\begin{aligned}
 \|2W - X\|_F^2 &= \|XW^T W - X\|_F^2 = \text{Tr}((XW^T W - X)^T (XW^T W - X)) \\
 &= \text{Tr}(W^T W X^T X W^T W) - 2\text{Tr}(W^T W X^T X) + \text{Tr}(X^T X) \\
 &= \text{Tr}(W^T \underbrace{W W^T}_I W X^T X) - 2\text{Tr}(W^T W X^T X) + \text{Tr}(X^T X) \\
 &= -\text{Tr}(W^T W X^T X) + (\text{constant})
 \end{aligned}$$

$\|A\|_F^2 = \text{Tr}(A^T A)$ Solved by same ‘W’
 $= XW^T$ ↑

Canonical Correlation Analysis (CCA)

- Suppose we have two matrices, ‘X’ and ‘Y’.
- Want to find matrices W_X and W_Y that maximize correlation.
 - “What are the latent factors in common between these datasets?”
- Define the correlation matrices:

$$\Sigma_{xx} = \frac{1}{n} \sum_{i=1}^n x_i x_i^\top \quad \Sigma_{yy} = \frac{1}{n} \sum_{i=1}^n y_i y_i^\top \quad \Sigma_{xy} = \frac{1}{n} \sum_{i=1}^n x_i y_i^\top$$

- Canonical correlation analysis (CCA) maximizes

$$\text{Tr}(W_Y^\top W_X \Sigma_{xx}^{-\frac{1}{2}} \Sigma_{xy} \Sigma_{yy}^{-\frac{1}{2}})$$

- Subject to W_X and W_Y having orthogonal rows.
- Computationally, equivalent to PCA with a different matrix.
 - Using the “analysis” view that PCA maximizes $\text{Tr}(W^\top W X^\top X)$.

Kernel PCA

- From the “analysis” view (with orthogonal PCs) PCA maximizes:

$$\text{Tr}(W^T W X^T X)$$

- It can be shown that the solution has the form (see [here](#)):

$$W = UX$$

$\underbrace{W}_{k \times d} \quad \underbrace{U}_{k \times n} \underbrace{X}_{n \times 1}$

- Re-parameterizing in terms of ‘U’ gives a [kernelized PCA](#):

$$\text{Tr}(X^T V^T V X X^T X) = \text{Tr}(V^T V X X^T X X^T)$$

$\underbrace{V^T V}_{K} \quad \underbrace{X X^T}_{K}$

- It’s hard to initially center data in ‘Z’ space, but you can [form the centered kernel matrix](#) (see [here](#)).

Probabilistic PCA

- With zero-mean (“centered”) data, in PCA we assume that

$$x_i \approx W^T z_i$$

- In **probabilistic PCA** we assume that

$$x_i \sim N(W^T z_i, \sigma^2 I) \quad z_i \sim N(0, I)$$

- Integrating over ‘Z’ the marginal likelihood given ‘W’ is Gaussian,

$$x_i | W \sim N(0, W^T W + \sigma^2 I)$$

- Regular PCA is obtained as the limit of σ^2 going to 0.

Generalizations of Probabilistic PCA

- Probabilistic PCA model:

$$x_i \mid W \sim \mathcal{N}(0, W^T W + \sigma^2 I)$$

- Why do we need a probabilistic interpretation?
- Shows that PCA fits a Gaussian with restricted covariance.
 - Hope is that $W^T W + \sigma^2 I$ is a good approximation of $X^T X$.
- Gives precise connection between PCA and factor analysis.

Factor Analysis

- Factor analysis is a method for discovering latent factors.
- Historical applications are measures of intelligence and personality.

Trait	Description
O penness	Being curious, original, intellectual, creative, and open to new ideas.
C onscientiousness	Being organized, systematic, punctual, achievement-oriented, and dependable.
E xtraversion	Being outgoing, talkative, sociable, and enjoying social situations.
A greeableness	Being affable, tolerant, sensitive, trusting, kind, and warm.
N euroticism	Being anxious, irritable, temperamental, and moody.

- A standard tool and widely-used across science and engineering.

PCA vs. Factor Analysis

- PCA and FA both write the matrix ‘X’ as

$$X \approx ZW$$

- PCA and FA are both based on a Gaussian assumption.
- Are PCA and FA the same?
 - Both are more than 100 years old.
 - People are still arguing about whether they are the same:
 - Doesn't help that some packages run PCA when you call their FA method.

Sep 28, 2009 - nents and factor analysis, we'll wrap up by looking at their uses and

PCA vs. Factor Analysis

- In probabilistic PCA we assume:

$$x_i \sim \mathcal{N}(W^\top z_i, \sigma^2 I)$$

- In FA we assume for a diagonal matrix D that:

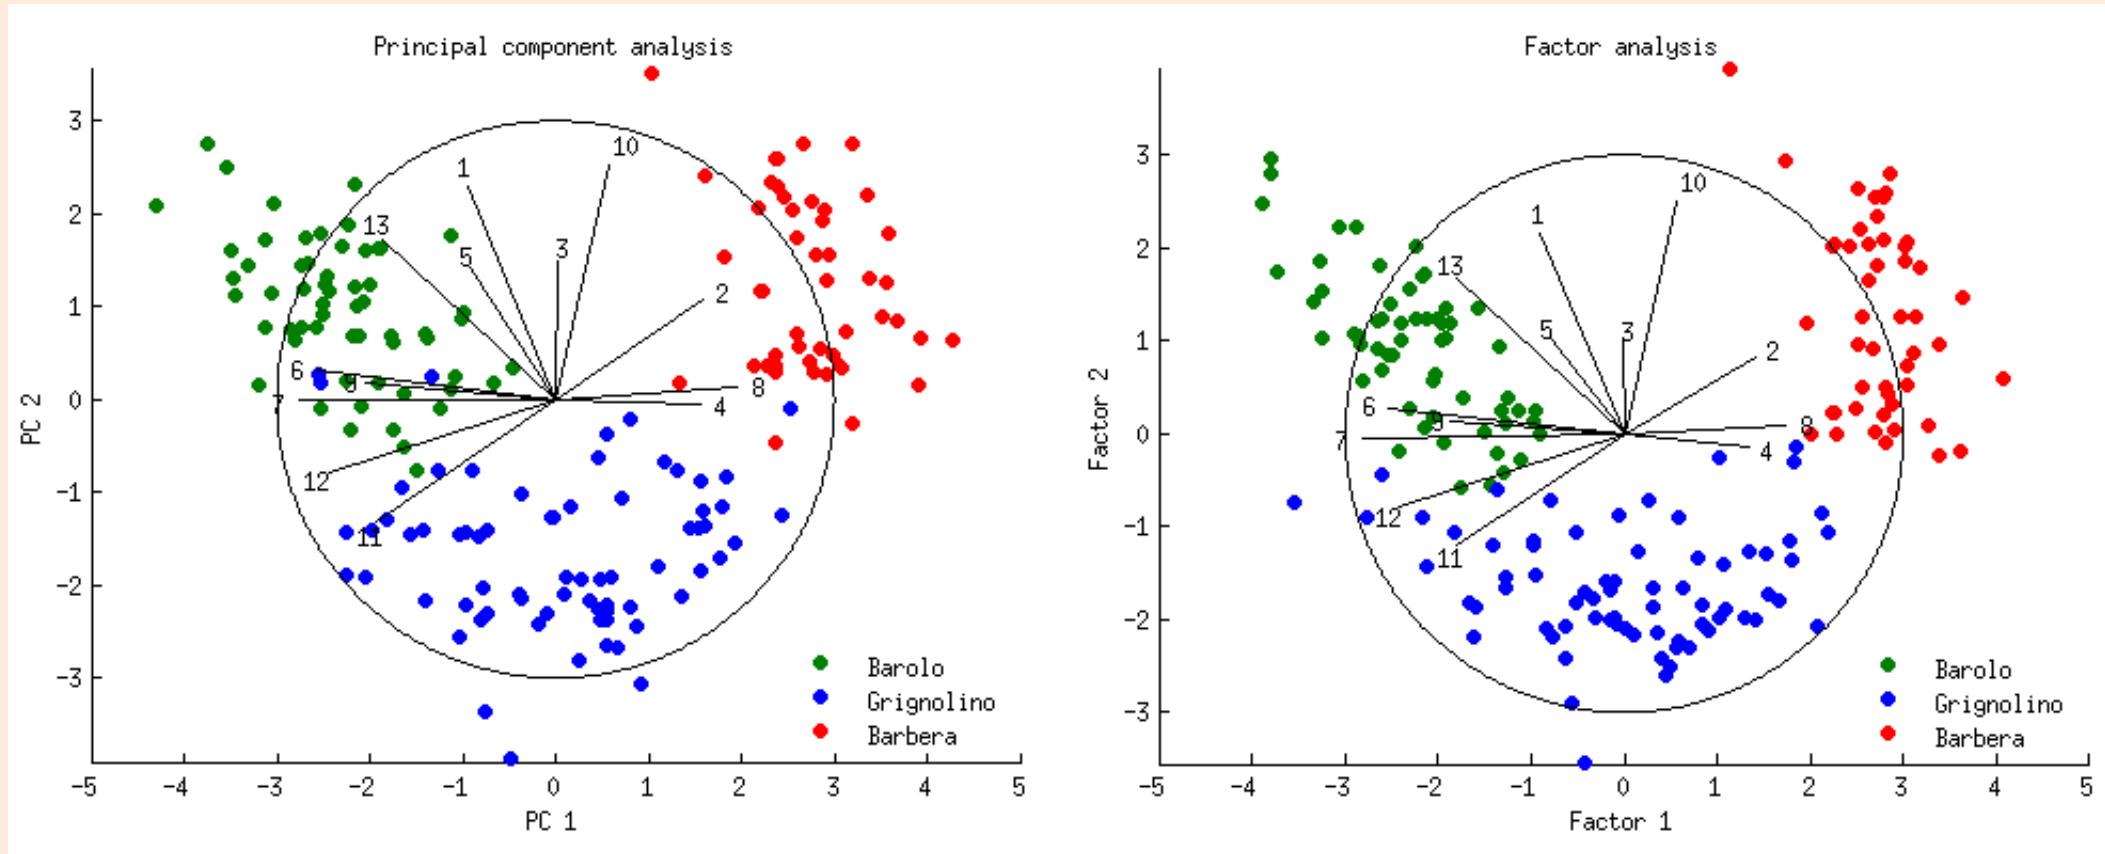

$$x_i \sim \mathcal{N}(W^\top z_i, D)$$

- The posterior in this case is: $x_i | W \sim \mathcal{N}(0, W^\top W + D)$
- The difference is you have a noise variance for each dimension.
 - FA has extra degrees of freedom.

PCA vs. Factor Analysis

- In practice there often isn't a huge difference:

Factor Analysis Discussion

- Differences with PCA:
 - Unlike PCA, FA is not affected by scaling individual features.
 - But unlike PCA, it's affected by rotation of the data.
 - No nice “SVD” approach for FA, you can get different local optima.
- Similar to PCA, FA is invariant to rotation of ‘W’.
 - So as with PCA you can't interpret multiple factors as being unique.

Motivation for ICA

- Factor analysis has found an enormous number of applications.
 - People really want to find the “hidden factors” that make up their data.
- But PCA and FA **can't identify the factors.**

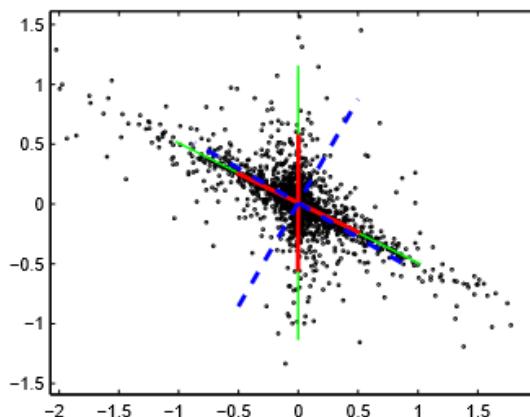

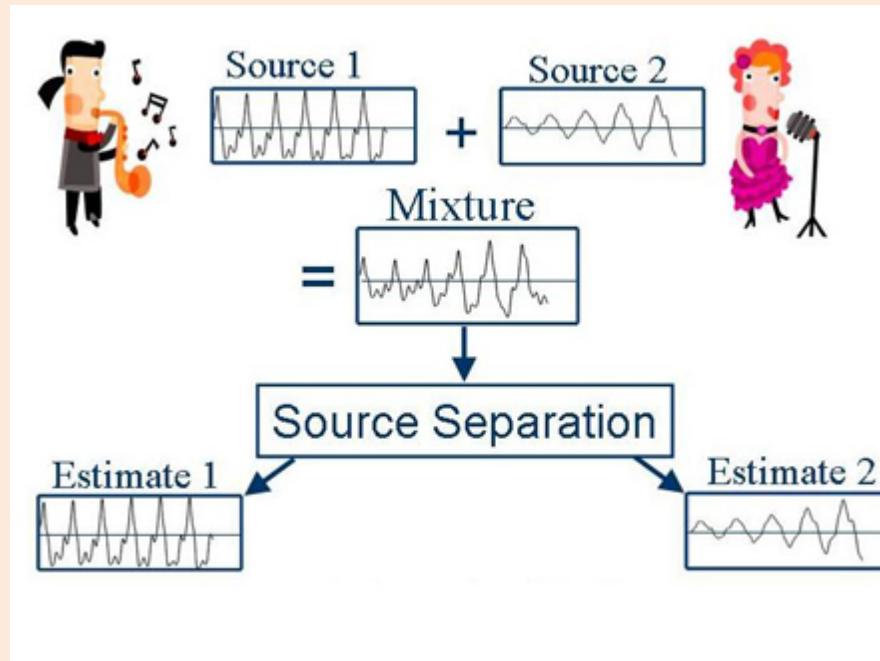

Figure : Latent data is sampled from the prior $p(x_i) \propto \exp(-5\sqrt{|x_i|})$ with the mixing matrix A shown in green to create the observed two dimensional vectors $y = Ax$. The red lines are the mixing matrix estimated by `ica.m` based on the observations. For comparison, PCA produces the blue (dashed) components. Note that the components have been scaled to improve visualisation. As expected, PCA finds the orthogonal directions of maximal variation. ICA however, correctly estimates the directions in which the components were independently generated.

Motivation for ICA

- Factor analysis has found an enormous number of applications.
 - People really want to find the “hidden factors” that make up their data.
- But PCA and FA **can't identify the factors**.
 - We can rotate W and obtain the same model.
- **Independent component analysis (ICA)** is a more recent approach.
 - Around 30 years old instead of > 100.
 - Under certain assumptions it can **identify factors**.
- The canonical application of ICA is **blind source separation**.

Blind Source Separation

- Input to blind source separation:
 - Multiple microphones recording multiple sources.

- Each microphone gets different mixture of the sources.
 - Goal is reconstruct sources (factors) from the measurements.

Independent Component Analysis Applications

- ICA is replacing PCA and FA in many applications:

Some ICA applications are listed below:^[1]

- optical Imaging of neurons^[17]
- neuronal spike sorting^[18]
- face recognition^[19]
- modeling receptive fields of primary visual neurons^[20]
- predicting stock market prices^[21]
- mobile phone communications^[22]
- color based detection of the ripeness of tomatoes^[23]
- removing artifacts, such as eye blinks, from EEG data.^[24]

- Recent work shows that ICA can often resolve direction of causality.

Limitations of Matrix Factorization

- ICA is a **matrix factorization** method like PCA/FA,

$$X = ZW$$

- Let's assume that $X = ZW$ for a "true" W with $k = d$.
 - Different from PCA where we assume $k \leq d$.
- There are only **3 issues** stopping us from finding "true" W .

3 Sources of Matrix Factorization Non-Uniqueness

- **Label switching:** get same model if we **permute rows** of W.
 - We can exchange row 1 and 2 of W (and same columns of Z).
 - Not a problem because we don't care about order of factors.
- **Scaling:** get same model if you **scale a row**.
 - If we multiply row 1 of W by α , could multiply column 1 of Z by $1/\alpha$.
 - Can't identify sign/scale, but might hope to identify direction.
- **Rotation:** get same model if we **rotate W**.
 - Rotations correspond to orthogonal matrices Q, such matrices have $Q^TQ = I$.
 - If we rotate W with Q, then we have $(QW)^TQW = W^TQ^TQW = W^TW$.
- **If we could address rotation, we could identify the “true” directions.**

A Unique Gaussian Property

- Consider an **independent prior** on each latent features z_c .
 - E.g., in PPCA and FA we use $N(0,1)$ for each z_c .
- If prior $p(z)$ is independent and **rotation-invariant** ($p(Qz) = p(z)$), then it must be Gaussian (only Gaussians have this property).
- The (non-intuitive) magic behind ICA:
 - If the priors are all **non-Gaussian**, it **isn't rotationally symmetric**.
 - In this case, we can **identify factors W** (up to permutations and scalings).

PCA vs. ICA

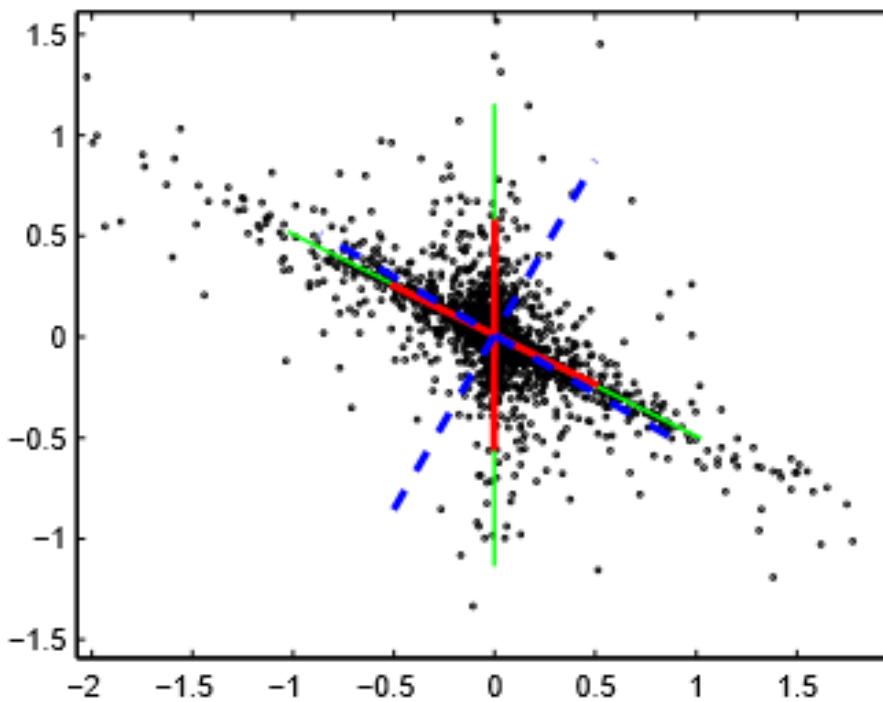

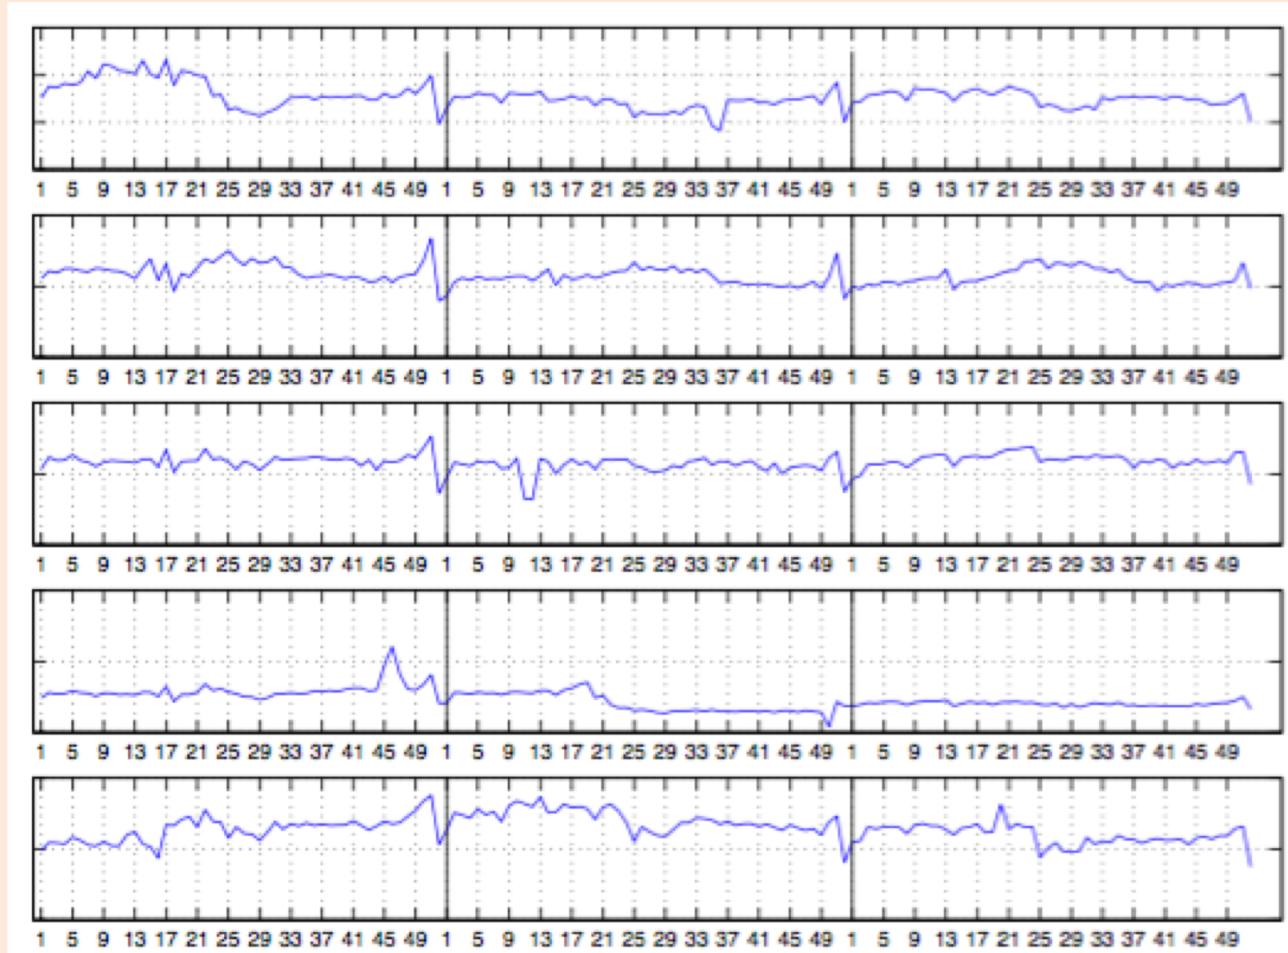

Figure : Latent data is sampled from the prior $p(x_i) \propto \exp(-5\sqrt{|x_i|})$ with the mixing matrix \mathbf{A} shown in green to create the observed two dimensional vectors $\mathbf{y} = \mathbf{Ax}$. The red lines are the mixing matrix estimated by `ica.m` based on the observations. For comparison, PCA produces the blue (dashed) components. Note that the components have been scaled to improve visualisation. As expected, PCA finds the orthogonal directions of maximal variation. ICA however, correctly estimates the directions in which the components were independently generated.

Independent Component Analysis

- In ICA we approximate X with ZW , assuming $p(z_{ic})$ are **non-Gaussian**.
- Usually we “center” and “whiten” the data before applying ICA.
- There are several penalties that encourage non-Gaussianity:
 - Penalize low **kurtosis**, since kurtosis is minimized by Gaussians.
 - Penalize high **entropy**, since entropy is maximized by Gaussians.
- The **fastICA** is a popular method maximizing kurtosis.

ICA on Retail Purchase Data
